

Each line is one cell of fixed  $(W, Q)$ , so fixed colour-frame kinematics, measured in three EIC beam configurations. The beam energy changes only the lab frame. Along each line the current hemisphere's lab momentum moves by up to a factor of ten and  $\langle n_{90} \rangle$  does not follow: median slope  $d \ln \langle n_{90} \rangle / d \ln p = -0.04$  per cell, against  $+0.28$  for the inclusive curve (grey). Marker shape encodes the  $Q$  bin, colour the  $W$  bin; each  $Q$  bin is drawn as one sheet spanned by beam energy and  $W$ .
