

The same cells and beam configurations for the leading anti- $k_T$  jet clustered in the laboratory at  $R = 1.2$ , the radius EIC studies use: median slope  $+0.011$ , against  $+0.22$  for the inclusive curve (grey). A plain lab cone of sensible size is already frame independent; the  $R = 0.4$  of the reference paper is the worst case, shown in the radius scan.
