

The same hemispheres in fixed (W, Q) cells across the three beam configurations, with n_{90} built from lab momenta (dark) and from colour-frame momenta (green). The particles are identical; only the frame in which they are ordered differs. Ordering in the lab leaves a residual slope of -0.050 because a large boost pushes the ordering towards light-cone momentum and concentrates the jet in fewer particles; ordering in the colour frame leaves -0.008 .
