

The same leading $R = 1.2$ lab jets, now with the IRC-safe iterated soft-drop multiplicity in its standard hadron-collider form (p_T fractions, rapidity-azimuth distance, $z_{cut} = 0.1$, $\Delta R_{cut} = 0.1$), evaluated on laboratory momenta as they are: median slope $+0.007$ across the beam configurations, against $+0.13$ for the inclusive curve (grey). No boost, no cone tuning, and an observable a calculation can be compared to.
