

Every rung is the same physics, measured differently, for n_{90} (circles) and the IRC-safe iterated soft-drop multiplicity n_{SD} (squares). Bars span individual (W, Q) cells across the 5×41 , 10×100 and 18×275 GeV configurations, which move the same colour-frame system through lab momenta differing by up to a factor of seven. Computing either observable from colour-frame momenta leaves no measurable dependence on the lab. The soft-drop squares use the e^+e^- form, with an absolute opening-angle cut, which a boost rescales; written the standard way for hadron collisions it is flat in the laboratory too, -0.016 (see sd'frame'choice).
